REFURBISHMENT
THE REPAIR AND PROTECTION OF REINFORCED CONCRETE WITH SIKA

IN ACCORDANCE WITH EUROPEAN STANDARDS EN 1504
Deterioration of concrete may happen due to corrosion, structural damage, water infiltration, freeze and thaw cycles, seismic activity, reactive aggregates etc. Years of research plus decades of practical experience have enabled Sika to develop a fully comprehensive solution to restore and rehabilitate concrete structures. Sika customer advice and support is second to none, from concept to successful completion on site. This is all based on more than 100 years of experience on large and small projects all over the world.

CONCRETE REPAIR AND PROTECTION
With corrosion management in reinforced concrete structures

THE EUROPEAN STANDARDS EN 1504 SERIES
The European Standards EN 1504 consist of 10 parts and is a systematic approach to rehabilitating concrete. With these documents products for the protection and repair of concrete structures are defined. Quality control of the repair materials production and the execution of the works on site are also all part of these standards.

| EN 1504 – 1 | Describes terms and definitions within the standard |
| EN 1504 – 2 | Provides specifications for surface protection products / systems for concrete |
| EN 1504 – 3 | Provides specifications for repairing concrete |
| EN 1504 – 4 | Provides specifications for structural bonding |
| EN 1504 – 5 | Provides specifications for concrete injection |
| EN 1504 – 6 | Provides specifications for anchoring of reinforcing steel bars |
| EN 1504 – 7 | Provides specifications for reinforcement corrosion protection |
| EN 1504 – 8 | Describes the quality control and evaluation of conformity for the manufacturing companies |
| EN 1504 – 9 | Defines the general principles for the use of products and systems, for the repair and protection of concrete |
| EN 1504 – 10 | Provides information on site applications of products and quality control of the works |

CE MARKING
The European Standards EN 1504 have been fully implemented since January, 2009. Existing National Standards which have not been harmonized with the new EN 1504 were withdrawn at the end of 2008 and CE Marking has become mandatory. Since July 2013 following CPR (Construction Product Regulation) all products used for concrete repair and protection now need to be described in document called Declaration of Performance (which must be prepared in local language) and respective CE marking (no specific language defined) must be assigned on the product label in accordance with the appropriate part of EN 1504. CE marking content is strictly defined by respective EU documents. It must be consistent with corresponding DOP and contains the following information – using the example of a concrete repair mortar suitable for structural use:

| CE marking symbol |
| DoP No. 49327793 |
| Sika Services AG, Zurich, Switzerland |
| EN 1504-3:2005 |
| Notified Body 1139, 1140 |

Structural and non-structural repair products for concrete for application in buildings and civil engineering work

- Compression strength ≥ 45 MPa
- Chloride ion content ≤ 0.05 %
- Adhesive bond ≥ 2.0 MPa
- Carbonation resistance Passed
- Elastic modulus ≥ 20 GPa
- Thermal compatibility freeze-thaw 2.0 MPa
- Capillary absorption ≤ 0.5 kg.m-2.h-0.5
- Reaction to fire Class A1

http://dop.sika.com

(Country-specific) DoP download center

Last 2 digits of the year in which the CE marking was first affixed
Unique identification code of the product-type (= reference number of the DOP)
Name and registered address of the manufacturer
No. of European harmonised standard applied as referenced in OJEU together with edition date
4 digits identification number of the Notified Body
Intended use as laid down in the applied harmonised European standard (hEN)
Level or class of the performance declared (as stated in the respective standard annex ZA)
CONCRETE REPAIR AND PROTECTION PROCESS – PROJECT PHASES
In Accordance with European Standard EN 1504-9

1 Information about the Structure

A study is carried out at the beginning of a project to collect information about the structure. This may include:
- General condition and history
- Documentation e.g. calculations, drawings and specifications etc.
- Repair and maintenance schedule

This information will provide valuable data to understand the existing condition of the structure.

2 Process of Assessment

In-depth condition survey shall be made of the visible and not readily visible defects of a structure to address the root causes of the damage. This will be used to assess the ability of the structure to perform its function.

The survey and its assessment shall only be carried out by a suitably qualified and experienced person.

In the event of not carrying out any repairs to the concrete structure a qualified Engineer may give an estimation of the remaining service life.

The aim of a concrete survey is to identify defects.
- Types of defects to the concrete
  - Mechanical
  - Chemical
  - Physical
- Defects in concrete due to reinforcement corrosion

3 Management Strategy

Based on the assessment of the survey, the owner has a number of options to be selected while deciding the relevant actions to meet the future requirements of the structure.

For example the repair options can be defined from the following:
- Do nothing or downgrade the capacity
- Prevent or reduce further damage without repair
- Repair all or part of the structure
- Reconstruction of all or part of the structure
- Demolition

Important factors when considering these options:
- Intended design life following repair and protection
- Required durability or performance
- Safety issues during repair works
- Possibility of further repair works in the future including access and maintenance
- Consequences and likelihood of structural failure
- Consequences and likelihood of partial failure

And environmentally:
- Protection from sun, rain, frost, wind, salt and/or other pollutants during the works
- Environmental impact of/or restrictions on the works in progress
- Noise and dust pollution
- Time needed to carry out the work etc.

Future maintenance:
Any future inspection and maintenance work that will need to be undertaken during the defined service life of the structure, shall also be defined as part of the management strategy.
Design of Repair Work

The relevant protection and repair principles will be defined from EN 1504-9 and the repair options contained in the management strategy.

The design philosophy for repair shall take into consideration the following:
- Type, causes and extend of defects
- Future service conditions
- Future maintenance program

Following the selection of the relevant principles from EN 1504-9, the Design Engineer shall also consider the intended use of the structure.

In the case of concrete refurbishment the specifications can be drawn up based on the requirements of the relevant parts 2 to 7 of EN 1504 (e.g. freeze and thaw cycles in external situations where appropriate).

It is important this work considers not only the long term performance of the structure, but also the affect of the selected materials on the rest of the structure i.e. no adverse affect.

Repair Work

Based on the relevant principles selected from EN 1504, the appropriate method of work is then based on:
- Site access
- Site conditions (e.g. selection of appropriate repair method – patch repair, pouring or spray application)
- Health and safety issues
- etc.

The surface preparation, application and Quality Control procedure for the repair works shall be carried out in accordance with the recommendations contained in Part 10 of EN 1504.

Acceptance of Repair Work

Complete records of all the materials used in the works shall be provided for future reference at the end of each project. These shall include the answer to these following issues:
- What is the anticipated new life expectancy?
- What is the mode and result of the selected materials eventual deterioration, i.e. chalking, embrittlement, discoloration or delamination?
- What is the inspection period?
- What remedial work might be required in case of deterioration?
# THE ROOT CAUSES OF CONCRETE DAMAGE AND DETORIATION

Assessment from the condition survey and the results of laboratory diagnosis

## CONCRETE DAMAGE DUE TO STEEL REINFORCEMENT CORROSION

### CHEMICAL ATTACK

**Cause**

Carbon dioxide (CO₂) in the atmosphere reacting with calcium hydroxide in the concrete pore liquid.

\[ \text{CO}_2 + \text{Ca(OH)}_2 \rightarrow \text{CaCO}_3 + \text{H}_2\text{O} \]

Soluble and strongly alkaline pH 12 – 13 → almost insoluble and much less alkaline pH 9.

Steel protected (passivation) → steel unprotected

**Relevant principles for repair and protection**

Principles 1, 2, 3, 7, 8, 11

### CORROSIVE CONTAMINANTS E.G. CHLORIDES

**Cause**

Chlorides accelerate the corrosion process and can also cause dangerous “pitting” corrosion.

At above 0.2 – 0.4% concentration in the concrete, chlorides can break down the passive oxide protective layer on the steel surface.

Chlorides are typically from marine/salt water exposure and/or the use of de-icing salts.

**Relevant principles for repair and protection**

Principles 1, 2, 3, 7, 8, 9, 11

### STRAY ELECTRICAL CURRENT

**Cause**

Metals of different electropotential are connected to each other in the concrete and corrosion occurs.

Corrosion can also be due to stray electrical currents from power supply and transmission networks.

**Relevant principles for repair and protection**

No specific Repair Principles defined at this time.

For repair of the concrete use Principles 2, 3, 10
AN OVERVIEW OF THE PRINCIPLES OF CONCRETE REPAIR AND PROTECTION ACCORDING EN-1504-9

THE PRINCIPLES RELATING TO CONCRETE DEFECTS

PRINCIPLE 1
Protection against ingress

PRINCIPLE 2
Moisture control

PRINCIPLE 3
Concrete restoration

PRINCIPLE 4
Structural strengthening

PRINCIPLE 5
Increasing physical resistance

PRINCIPLE 6
Resistance to chemicals
The repair and protection of concrete structures require relatively complex assessment and design. By introducing and defining the key principles of repair and protection, EN 1504-9 helps owners and construction professionals to fully understand the problems and solutions throughout the different stages of the repair and protection process.
THE PRINCIPLES OF CONCRETE REPAIR AND PROTECTION

WHY PRINCIPLES?

For many years, the different types of damage and the root causes of this damage have been well known and equally the correct repair and protection methods have also been established. All of this knowledge and expertise is now summarized and clearly set out as 11 Principles in EN 1504, Part 9. These allow the Engineer to correctly repair and protect all of the potential damage that can occur in reinforced concrete structures. Principles 1 to 6 relate to defects in the concrete itself, Principles 7 to 11 relate to damage due to reinforcement corrosion.

The European Union fully introduced all of the European Standards 1504 in January 2009. These Standards define the assessment and diagnostic work required, the necessary products and systems including their performance, the alternative procedures and application methods, together with the quality control of the materials and the works on site.

THE USE OF THE EN 1504 PRINCIPLES

To assist Owners, Engineers and Contractors with the correct selection of repair Principles, Methods and then the appropriate products, together with their specification and use, Sika has developed a useful schematic system of approach. This is designed to meet the individual requirements of a structure, its exposure and use are illustrated on pages 44 to 47 of this brochure.
EXPERTISE AND EXPERIENCE FROM SIKA

THE SIKA SOLUTIONS IN ACCORDANCE WITH EN 1504

Sika is a global market and technology leader in the development and production of specialist products and systems for construction. The “Repair and Protection” of concrete structures is one of Sika’s core competencies, with the Sika range including concrete admixtures, resin flooring and coating systems, all types of waterproofing solutions, sealing, bonding and strengthening solutions, as well as the complete range of products developed specifically for the repair and protection of concrete structures. These Sika products have all relevant international approvals and are available worldwide through the local Sika companies and our specialist contracting and distribution partners.

During the past 100 years, Sika has gained extensive experience and expertise in all aspects of concrete repair and protection, with documented project references dating back to the 1920’s. Sika provides ALL of the necessary products for the technically correct repair and protection of concrete, ALL of which are fully in accordance with the Principles and Methods now defined in European Standards EN 1504. These include systems to repair damage and defects in the concrete and also to repair damage caused by steel reinforcement corrosion. Special Sika products and systems are also available for use on many different specific types of structures and for carrying out concrete repair works in all different application, climatic and exposure conditions.
AN OVERVIEW OF THE PRINCIPLES AND METHODS OF REPAIR AND PROTECTION FROM EN 1504-9

Tables 1 and 2 include all of the repair Principles and Methods in accordance with Part 9 of EN 1504. Following assessment from the condition survey and diagnosis of the root causes of damage, together with the owners repair objectives and requirements, the appropriate EN 1504 repair Principles and Methods can be selected.

EN 1504-9 PRINCIPLE 1: PROTECTION AGAINST INGRESS

Protecting the concrete surface against liquid and gaseous ingress

A large amount of concrete damage is the result of the penetration of deleterious materials into the concrete, including both liquid and gaseous materials. The Principle 1 Protection Against Ingress deals with preventing this ingress and includes methods to reduce the concrete permeability and porosity of the concrete surfaces to these different materials.

The selection of the most appropriate method is dependent on different parameters, including the type of deleterious material, the quality of the existing concrete and its surface, the objectives of the repair or protection works and the maintenance strategy.

Sika produces a full range of impregnations, hydrophobic impregnations and specialized coatings for use in protecting concrete according to the Principles and Methods of EN 1504.

A hydrophobic impregnation is defined as the treatment of concrete to produce a water-repellent surface. The pores and capillary network are not filled, but only lined with the hydrophobic material. This functions by reducing the surface tension of liquid water, preventing its passage through the pores, but still allowing each way water vapour diffusion, which is in accordance with standard good practice in building physics.

An impregnation is defined as the treatment of concrete to reduce the surface porosity and to strengthen the surface. The pores and capillaries are then partly or totally filled. This type of treatment usually also results in a discontinuous thin film of 10 to 100 microns thickness on the surface. This serves to block the pore system to aggressive agents.

Surface coatings are defined as materials designed to provide an improved concrete surface, for increased resistance or performance against specific external influences. Fine surface cracks with a total movement of up to 0.3 mm can be safely repaired, then sealed and their movement accommodated by the use of elastic, crack bridging coatings, which are also waterproof and carbonation resistant. This will accommodate thermal and dynamic movement in structures subject to wide temperature fluctuations, vibration, or that have been constructed with inadequate or insufficient jointing details.

Sikagard®-675 W Elastocolor  
- Acrylic resin, water dispersed  
- Concrete protection  |
All concrete protection works must take account of the position and size of any cracks and joints in the concrete. This means investigating their nature and cause, understanding the extent of any movement in the substrate and its effect on the stability, durability and function of the structure, as well as evaluating the risk of creating new cracks as a result of any remedial joint or crack treatment and repair.

If the crack has implications for the integrity and safety of a structure, refer to Principle 4 Structural strengthening, Methods 4.5 and 4.6 on Page 28/29. This decision must always be taken by the structural engineer and then the selected surface treatments can then be applied successfully.

### EN 1504-9 PRINCIPLE 1: PROTECTION AGAINST INGRESS

Protecting the concrete surface against liquid and gaseous ingress (continued)
All concrete protection works must take account of the position and size of any cracks and joints in the concrete. This means investigating their nature and cause, understanding the extent of any movement in the substrate and its effect on the stability, durability and function of the structure, as well as evaluating the risk of creating new cracks as a result of any remedial joint or crack treatment and repair.

If the crack has implications for the integrity and safety of a structure, refer to Principle 4 Structural strengthening, Methods 4.5 and 4.6 on Page 28/29. This decision must always be taken by the structural engineer and then the selected surface treatments can then be applied successfully.

### Methods Applications

<table>

| Locally applying a suitable material to prevent the ingress of aggressive media into the concrete. | No specific criteria | Sikadur®-Combiflex® System  
- Extremely flexible  
- Weather and water resistant  
- Excellent adhesion  
Sika® SealTape-S  
- High elasticity  
- Waterproof |
| Cracks to be treated to prevent the passage of aggressive agents should be filled and sealed.  
Non-moving cracks - These are cracks that have been formed by initial shrinkage for example, they need only to be fully exposed and repaired / filled with a suitable repair material. | Classification of injection materials:  
D: ductile  
S: swelling | Waterproof Sealing of Joints/Cracks/Voids:  
Class D:  
Sika® Injection-201/-203  
Class S:  
Sika® Injection-29/-304/-305 |
| Cracks to be treated to accommodate movement should be repaired so that a joint is formed to extend through the full depth of the repair and positioned to accommodate that movement. The cracks (joints) must then be filled, sealed or covered with a suitably elastic or flexible material. The decision to transfer a crack to the function of a movement joint must be made by a structural engineer. | No specific criteria | Sikaflex® PU and AT- ranges  
- One-component polyurethanes  
- High movement capability  
- Excellent durability  
Sikadur®-Combiflex® System  
- Extremely flexible  
- Weather and water resistant  
- Excellent adhesion |
| Protecting the concrete surface with external Panels. A curtain wall or similar external façade cladding system, protects the concrete surface from external weathering and aggressive materials attack or ingress. | No specific criteria | SikaTack®-Panel System  
- For the discrete or ‘secret fixing’ of Curtain wall façade systems  
- One-component polyurethane |
| Applying a preformed sheet or liquid applied membrane over the concrete surface will fully protect the surface against the attack or ingress of deleterious materials. Fully bonded membranes limit surface damage to a minimum and due to the full bond, lateral water migration is prevented. | No specific criteria | SikaProof® fully bonded membrane  
Sikaplan® sheet membranes  
- Full surface waterproofing  
Sikalastic®-851 liquid membrane  
- Waterproofing  
- Particularly useful for complex details |
EN 1504-9 PRINCIPLE 2: MOISTURE CONTROL
Adjusting and maintaining the moisture content in the concrete

In some situations, such as where there is a risk of further alkali aggregate reaction, the concrete structure has to be protected against water penetration.

This can be achieved by the use of different types of products including hydrophobic impregnations, surface coatings and electrochemical treatments.

For many years, Sika has been one of the pioneers in concrete protection through the use of deeply penetrating silane and siloxane hydrophobic impregnations, plus durable acrylic and other resin based protective coatings.

Several of these are also tested and approved for use in conjunction with the latest electrochemical treatment techniques.

All of these Sika systems for the Method "Moisture Control" are fully in accordance with the requirements of EN 1504.

Sikagard®-704 S (Class I)  
Sikagard®-740 W (Class I)  
Sikagard®-700 S (Class I) |
| A hydrophobic impregnation is defined as the treatment of concrete to produce a water-repellent surface. The pores and capillary network are not filled, but only lined with the hydrophobic material. This function by reducing the surface tension of liquid water, thus preventing its passage through the pores, but still allowing each way water vapour diffusion, which is in accordance with standard good practice in building physics. | Penetration depth: ≥5 mm Capillary absorption: \( w <0.1 \text{kg/(m}^2 \times \sqrt{h}) \) | Sikafloor®-CureHard-24  
- Sodium silicate base  
- Excellent abrasion and surface hardening  
- Greater densification capacity  
Sikafloor®-CureHard-LI  
- Lithium silicate base  
- Increased penetration and aesthetics  
- Reduced application costs |
| An impregnation is defined as the treatment of concrete to reduce the surface porosity and to strengthen the surface. The pores and capillaries are then partly or totally filled. This type of treatment usually also results in a discontinuous thin film of 10 to 100 microns thickness on the surface. This serves to block the pore system to aggressive agents. | Capillary absorption: \( w <0.1 \text{kg/(m}^2 \times \sqrt{h}) \) | Sikagard®-680 S  
- Acrylic resin, solvent dispersed  
Sikagard® Wallcoat T  
- 2 part epoxy, water dispersed  
- Tunnel protective coating  
Sikagard®-550 W Elastic  
- Acrylic resin, water dispersed  
- Concrete protection and crack-bridging  
Sikagard®-545 W Elastofill  
- Acrylic resin, water dispersed  
- Elastic system base coat  
Sikagard®-675 W Elastocolor  
- Acrylic resin, water dispersed  
- Concrete protection |
| Surface coatings are defined as materials designed to provide an improved concrete surface, for increased resistance or performance against specific external influences. Fine surface cracks with a total movement of up to 0.3 mm can be safely repaired, then sealed and their movement accommodated by crack bridging coatings which are also for waterproof and carbonation resistant. | Water vapour permeability: Class I: \( Sd <5 \text{m} \) Adhesion strength: Elastic: ≥0.8 \( \text{N/mm}^2 \) or ≥1.5 \( \text{N/mm}^2 \) (trafficking) Rigid: ≥1.0 \( \text{N/mm}^2 \) or ≥2.0 \( \text{N/mm}^2 \) (trafficking) | Sikagard®-680 S  
- Acrylic resin, solvent dispersed  
Sikagard® Wallcoat T  
- 2 part epoxy, water dispersed  
- Tunnel protective coating  
Sikagard®-550 W Elastic  
- Acrylic resin, water dispersed  
- Concrete protection and crack-bridging  
Sikagard®-545 W Elastofill  
- Acrylic resin, water dispersed  
- Elastic system base coat  
Sikagard®-675 W Elastocolor  
- Acrylic resin, water dispersed  
- Concrete protection |
| As long as the concrete surface is not exposed, no water can penetrate and the reinforcement can not corrode. | No specific criteria | SikaTack®-Panel System  
- For the discrete or ‘secret fixing’ of curtain wall facade systems  
- One-component polyurethane |
| By applying an electric potential in the structure, moisture can be moved towards the negatively charged cathode area. | No specific criteria | This is a process |
EN 1504-9 PRINCIPLE 3: CONCRETE RESTORATION
Replacing and restoring damaged concrete

The selection of the appropriate method of replacing and restoring concrete depends on a number of parameters including:

- The extent of damage (e.g. Method 3.1 Hand-applied mortar, is more economic for limited damage)
- Congestion of rebar (e.g. Method 3.2 Recasting with concrete or mortar is usually to be preferred in the presence of heavily congested bars).

- Extremely low shrinkage behaviour  
- Lightweight repair mortar  
- Applied by hand or “wet” spray applied |
| Today in addition to traditional dry spray machines, there are also “wet spray” machines. These have a lower volume output, but also much lower rebound, plus they produce less dust than the dry spray machines. Therefore they can also be used economically for smaller or more sensitive repair areas, where there is restricted access, or in confined environments. | | |
| The most important application criteria for sprayed repair materials are minimal rebound, plus high-build properties to achieve the required non-sag layer thickness. Application under dynamic load and minimal or easy finishing and curing, are also important due to their areas of use and the difficulties in access. | | |
| In some situations it can be more economical to replace either the whole structure or part of it, rather than to carry out extensive repair works. In this situation, care needs to be taken to provide appropriate structural support and load distribution during the works, for example by using suitable bonding systems or agents to ensure this is maintained. | No specific criteria | System consisting of Sika® bonding primer and Sika® concrete technology

EN 1504-9 PRINCIPLE 4:
STRUCTURAL STRENGTHENING
Increasing or restoring the structural load capacity

Whenever there is a need for structural strengthening due to a change of the structures designation, or to an increase in the structural load bearing capacity for example, the appropriate analysis must be performed by a qualified structural engineer. Various methods are available to achieve the necessary strengthening and these include: adding external support or embedded reinforcement, by bonding external plates, or by increasing the dimensions of the structure.

The selection of the appropriate method is dependant on the different project parameters such as the type of structure, cost, site environment and conditions, plus access and maintenance possibilities etc.

Sika has pioneered the development of many new materials and techniques in the field of structural strengthening. Since the early 1960’s this has included the development of steel plate bonding and epoxy structural adhesives. In the 1990’s Sika began working on the adaptation of these techniques using modern composite materials, particularly pultruded carbon fibre plates (Sika CarboDur®).

Since then, Sika has further developed this technology by using unidirectional fabrics (SikaWrap®) based on several different fibre types (carbon, glass, etc.).

Injecting and sealing cracks generally does not structurally strengthen a structure. However, for remedial work or when temporary overloading has occurred, the injection of low viscous epoxy resin based materials can restore the structure to its original structural condition.

The introduction of prestressed composites for reinforcement has brought this technology to another level. This uses high strength, lightweight carbon fibre reinforced plates, plus curing times are reduced and the application conditions can be extended through innovative electrical heating of the adhesive.

These innovations serve to further demonstrate that Sika is the clear global leader in this field.

Prestressing: with this method the system involves applying forces to a structure to deform it in such a way that it will withstand its working loads more effectively, or with less total deflection. (Note: post-tensioning is a method of prestressing a poured in place concrete structure after the concrete has hardened).

An impregnation is defined as the treatment of concrete to reduce the surface porosity and to strengthen the surface. The pores and capillaries are partly or totally filled. This type of treatment also usually result in a discontinuous thin film of 10 to 100 microns thickness on the surface. Certain impregnations can react with some of the concrete constituents to result in higher resistance to abrasion and mechanical attack.

EN 1504-9 PRINCIPLE 6: CHEMICAL RESISTANCE
Increasing the concrete's resistance to chemical attack

The chemical resistance requirements of a concrete structure and its surfaces are dependent on many parameters including the type and concentration of the chemicals, the temperatures and the likely duration of exposure, etc. Appropriate assessment of the risks is a prerequisite to allowing the correct protection strategy to be developed for any specific area.

Different types of protective coatings are available from Sika to provide full or short term chemical resistance, according to the type and degree of exposure.

Sika therefore provides a full range of protective coatings to protect concrete in all different chemical environments. These are based on many different resins and materials including: acrylic, epoxy, polyurethane silicate, epoxy-cement combinations, polymer modified cement mortars, etc..

EN 1504-9 PRINCIPLE 7: PRESERVING OR RESTORING PASSIVITY

Treating or replacing concrete surrounding the reinforcement

Corrosion of the reinforcing steel in a concrete structure only happens when various conditions are met: loss of passivity, the presence of oxygen and the presence of sufficient moisture in the surrounding concrete.

If one of these conditions is not met, then corrosion cannot occur. In normal conditions, the reinforcement steel is protected from the alkalinity surrounding the concrete cover. This alkalinity creates a passive film of oxide on the steel surface which protects the steel from corrosion.

However, this passive film can be damaged due to the reduction of the alkalinity by carbonation when the carbonation front has reached the reinforcement steel. A break-down also occurs due to chloride attack. In both these instances, the protecting passivation is then lost. Different methods to reinstate (or to preserve) the passivity of the reinforcement are available.

The selection of the appropriate method will depend on various parameters such as: the reasons for the loss of passivation (e.g. due to carbonation or chloride attack), the extent of the damage, the specific site conditions, the repair and protection strategy, maintenance possibilities, costs, etc.

Sika concrete technology for quality concrete replacement: Sika® ViscoCrete®  
Sikament® |
| **Realalkalisation of concrete structures by electrochemical treatment** is a process performed by applying an electric current between the embedded reinforcement to an external anode mesh, which is embedded in an electrolytic reservoir, placed temporarily on the concrete surface. This treatment does not prevent the future ingress of carbon dioxide. So to be effective on the long term, it also needs to be combined with appropriate protective coatings that prevent future carbonation and chloride ingress. | No specific criteria | For post-treatment: Sika® ViscoCrete®  
Sikament®  
For post-treatment: Sikagard®-720 EpoCem®  
Sikagard®-680 S or Sikagard®-690 W HD |
| There is limited long term experience with this method. It requires the application of a very alkaline coating over the carbonated concrete surface and the realalkalisation is achieved by the slow diffusion of the alkalai through the carbonated zone. This process takes a very long time and it is very difficult to control the right distribution of the material. After treatment, it is also always recommended to prevent further carbonation by applying a suitable protective coating. | No specific criteria | For post-treatment: Sika® ViscoCrete®  
Sikament®  
For post-treatment: Sikagard®-680 S or Sikagard®-690 W HD |
| The electrochemical chloride extraction process is very similar in nature to cathodic protection. The process involves the application of an electrical current between the embedded reinforcement and an anode mesh placed at the outer surface of the concrete structure. As a result, the chlorides are driven out toward the surface. Once the treatment is completed, the concrete structure has to be protected with a suitable treatment to prevent the further ingress of chlorides (post treatment). | No specific criteria | For post-treatment: penetrating hydrophobic impregnation with Sikagard®-705 L or Sikagard®-706 Thixo  
plus protective coating Sikagard®-680 S or Sikagard®-675 W ElastoColor |
EN 1504-9 PRINCIPLE 8: INCREASING RESISTIVITY

Increasing the electrical resistivity of the concrete to reduce the risk of corrosion

Principle 8 deals with increasing the resistivity of the concrete, which is directly connected to the level of moisture available in the concrete pores. The higher the resistivity, the lower is the amount of free moisture available in the pores.

This means that reinforced concrete with high resistivity will have a low corrosion risk.

Principle 8 deals with the increase of the concrete’s electrical resistivity, therefore then covers almost the same Methods of repair as Principle 2 Moisture Control.

EN 1504-9 PRINCIPLE 9: CATHODIC CONTROL
Preventing corrosion of the steel reinforcement

Principle 9 relies upon restricting the access of oxygen to all potentially cathodic areas, to the point when corrosion is prevented.

An example of this is to limit the available oxygen content by the use of coatings on the steel surface.

Another is the application of an inhibitor in sufficient quantities, that can form a film on the steel surface which acts as a barrier to block access to oxygen.

EN 1504-9 PRINCIPLE 10: CATHODIC PROTECTION
Preventing corrosion of the steel reinforcement

Principle 10 refers to cathodic protection systems. These are electrochemical systems which decrease the corrosion potential to a level where the rate of the reinforcing steel dissolution is significantly reduced. This can be achieved by creating a direct electric current flow from the surrounding concrete to the reinforcing steel, in order to eliminate the anodic parts of the corrosion reaction. This current is provided by an external source (Induced Current Cathodic Protection), or by creating a galvanic current through connecting the steel to a less noble / more reactive metal (galvanic anodes e.g. zinc).

</tbody>
</table>
In considering the control of anodic areas to prevent corrosion with Principle 11, it is important to understand that particularly in heavily chloride contaminated structures, spalling due to reinforcement corrosion happens first in areas of low concrete cover. Additionally it is also important to protect repaired areas from the future ingress of aggressive agents (carbonation, chlorides).

A protective cement slurry can be applied directly on the reinforcement after appropriate cleaning, to prevent further steel dissolution at the anodic areas.

Additionally, to protect against the formation of incipient anodes in the areas surrounding the patch repairs, a corrosion inhibitor can be applied to migrate through the concrete and reach the reinforcement, where it forms a barrier, also protecting the anodic zones.

Note: Dual function inhibitors such as Sika® FerroGard® also protect the cathodic areas simultaneously.

</table>
| These coatings contain active pigments that can function as an inhibitor or/and provide a passive environment due to their alkalinity. Although care must be taken to apply them properly, they are less sensitive to application defects than barrier coatings. | Compliance with EN 1504-7                                                      | Cement based: Sika MonoTop®-310 N  
  - 1-component corrosion protection  
  - Good resistance to water and chloride penetration  
  Epoxy modified cement based: SikaTop® Armatec®-110 EpoCem®  
  - High density, suitable for demanding environments  
  - Excellent adhesion to steel and concrete |
| These barrier coatings work by completely isolating the reinforcement from oxygen or water. Therefore they require higher levels of surface preparation and application control. This is because they can only be effective if the steel is completely free from corrosion and fully coated without any defects – this can be very difficult to achieve in site conditions. Any effective reduction in the bonding of the repair material to the treated reinforcement should also be considered. | Compliance with EN 1504-7                                                      | Epoxy based: Sikadur®-32  
  - Low sensitivity to moisture  
  - Very dense, no chloride penetration |
| Applying corrosion inhibitors to the concrete surface, they diffuse to the reinforcement and form a protective layer on the surface of the bars. These corrosion inhibitors can also be added as admixtures to the repair mortar or concrete that is used for the concrete reinstatement works. | Sika recommendation of:  
  >100 ppm (parts per million) concentration of corrosion inhibitor at the rebar level in the presence of chlorides. | Corrosion inhibitors: Sika® FerroGard®-901  
  (admixture)  
  Sika® FerroGard®-903 Plus  
  (surface applied)  
  - Amino alcohol based inhibitors  
  - Long term protection and durability  
  - Economic extension of the service life of reinforced concrete structures |

EN 1504 Parts 2–7 and EN 1504-9, Clauses 6, 7 and 9
EN 1504-9, Clause 9 and 10 and EN 1504-10
EN 1504-9, Clause 8 and EN 1504-10
In the matrix tables below the most common defects and damage of concrete structures and their possible repair methods are listed. This list is intended to be indicative rather than exhaustive. The repair proposals must be customised according to the specific conditions on each project. Deviations from this matrix of outline recommendations are therefore possible and these must be determined individually for each situation. The numbers indicated in the tables are reference to the relevant Principles and Methods defined in EN 1504-9.

### DAMAGE TO CONCRETE

3.1 Recasting with concrete or mortar | 3.2 Recasting with concrete or mortar  
3.3 Spraying concrete or mortar | 3.2 Recasting with concrete or mortar  
4.1 Adding or replacing embedded or external reinforcing bars  
3.3 Spraying concrete or mortar  
4.2 Adding reinforcement anchored in pre-formed or drilled holes |
The overall protection required for concrete structures as well as that required for their embedded steel reinforcement, is dependent on the type of structure, its environmental exposure and location, its use and the selected maintenance strategy. Therefore protection proposals should be adapted to individual structures, their specific conditions and their specific requirements. Deviations from these outline recommendations are therefore possible and should always be determined on each individual project. The prefix numbers in the following tables are the references of the relevant Principles and Methods of EN 1504-9.

### Protection to Concrete

Sika uses specific in-house and independent testing and assessment criteria to evaluate all of its products and systems for concrete repair and protection, which are fully in accordance with the requirements of the appropriate parts and sections of European Standards EN 1504 (Parts 2 – 7). The Sika Product and System Testing and Assessment criteria for these concrete repair and protection materials are as follows:

**FOR CONCRETE REPAIRS**

- Protecting exposed reinforcement
  - Bond strength to steel and concrete
  - Corrosion protection
  - Permeability to water
  - Permeability to water vapour
  - Permeability to carbon dioxide
  - Chloride permeability

- Levelling the profile and filling surface pores
  - Bond strength
  - Permeability to carbon dioxide
  - Permeability and absorption of water
  - etc.

- Replacing damaged concrete
  - Bond strength
  - Compressive and flexural strengths
  - Permeability to water
  - Elastic modulus (stiffness)
  - Restraint shrinkage
  - Thermal compatibility
  - etc.

**FOR CONCRETE PROTECTION**

- Moisture control with hydrophobic impregnations
  - Penetration depth
  - Water absorption
  - Alkali resistance
  - Water vapour permeability
  - Freeze / thaw resistance
  - Chloride penetration

- Rigid protective coatings
  - Bond strength
  - Cross-cut test
  - Permeability to carbon dioxide
  - Permeability to water vapour
  - UV light resistance
  - Alkaline substrate resistance
  - Freeze/thaw resistance
  - Fire behavior
  - etc.

- Elastic protective coatings
  - Crack-bridging ability
    - Static
    - Dynamic
    - At low temperatures (-20 °C / -4 °F)
  - Bond strength
  - Cross-cut test
  - Permeability to carbon dioxide
  - Permeability to water vapour
  - UV light resistance
  - Alkaline substrate resistance
  - Freeze / thaw resistance
  - Fire behavior
  - etc.
PERFORMANCE CRITERIA

Product and System Performance
There are functional and performance requirements which must be met by both the individual products as components of a system and the system functioning together as a whole.

Practical Application Criteria of the Performance
In addition to their performance in place on the structure, it is also essential to define and then test the application characteristics and properties of the products. At Sika we ensure that these are in accordance with the guidelines of EN 1504 Part 10, but additionally we also ensure that Sika products can all be applied practically on site and in all of the differing climatic conditions that will be encountered around the world.

For example:
Sika repair mortars must be suitable for use in differing thicknesses, areas and volumes of repair, which need to be applied in as few layers as possible. They must then rapidly become weather resistant.
Equally Sikagard® coatings must have adequate viscosity and the right thixotropic properties at different temperatures, in order to obtain the desired wet and dry film thicknesses. This should be achieved in the minimum number of coats, plus they must also achieve adequate opacity and become weather resistant quickly.

QUALITY ASSURANCE

Quality Control in Production
It is also necessary for any product or system to meet well defined Quality Assurance and Quality Control standards in production. Contained in European Standard EN 1504 Part 2 to 7 are the relevant requirements for quality control in the production plant. In addition to these requirements, compulsory in Europe, Sika is accredited to ISO 9001 in all production facilities throughout the world.

Quality Control on Site
More and more important repair work requires an established Quality Assurance plan. With knowledge in quality management, Sika can help the contractor to work out and prepare the relevant procedures to comply with all these requirements.
EN 1504-10 gives guidance regarding the relevant Quality Control to be carried out on site. Sika also publishes product and system specification details together with method statements for applying the product on site. Quality Control Procedures and checklists are available to support the site supervisor and overall management of concrete repair and protection projects.
ASSESSMENTS OF SIKA PRODUCTS AND SYSTEMS
Additional Performance Testing and the Extensive Independent Durability

CONCRETE REPAIRS

The “Baenziger Block” for Mortar Testing
There are many reported causes of premature failures in repair mortar, but one of the most common is cracks forming in the material. For a long time Sika has recognised this issue and developed a practical test procedure to push performance limits and improve product quality.
The “Baenziger Block” has now been assessed as the optimal specification and configuration for evaluating the sensitivity of repair materials by the USA Department of the Interior CREE Programme.

Sika advanced repair mortar product performance testing
The “Baenziger Block” for concrete repair mortars testing allows direct comparisons and measurements of performance between products, production methods, production facilities and application conditions everywhere in the world.

This Sika innovation allows:
- Direct comparison worldwide
- Application horizontal, vertical and overhead
- Realistic site dimensions
- Additional lab testing by coring
- Shrinkage and performance crack testing

Testing Product Application under Dynamic Load
Application for installation and performance testing of repair mortars under live dynamic loading.

The Real Proof on Real Structures – Independent Evaluation of Completed Projects
A major international study of completed repair projects by inspection, testing and review was undertaken in 1997 by leading independent consultants and testing institutes.

This involved more than twenty major buildings and civil engineering structures in Norway, Denmark, Germany, Switzerland and the United Kingdom which were repaired and protected with Sika systems between 1977 and 1986. These were re-inspected and their condition and the repair systems’ performance assessed after periods from 10 to 20 years by leading consultants specializing in this field.

The excellent condition of the structures and the materials performance reports that were the conclusions of these engineers, provide a clear and unequivocal testimony for Sika’s concrete repair and protection products. They also confirm Sika’s pioneering work in the early development of the modern, systematic approach to concrete repair and protection.

These reports are available in a printed Sika reference document “Quality and Durability in Concrete Repair and Protection”. 
CONCRETE PROTECTION

Testing the Performance of Corrosion Inhibitors
Sika has introduced Surface Applied Corrosion Inhibitors in 1997. Since then, millions of square metres of reinforced concrete have been protected from corrosion all over the world. Sika® FerroGard®-903+ covers the Principle 9 (Cathodic control) and Principle 11 (Anodic control). Since this introduction many studies have confirmed the efficiency of the corrosion protection afforded by this technology.

The latest international reports, amongst many available from leading institutions worldwide, are from the University of Cape Town South Africa, showing its efficiency in carbonated structures. From the Building Research Establishment (BRE) showing the effectiveness of Sika® FerroGard®-903+ applied as a preventative measure in a heavily chloride contaminated environment. This performance was monitored and evaluated over a 2.5 year programme (BRE 224-346A).

Additionally there is the European SAMARIS project begun in 2002 which forms part of the major European Community research project: Sustainable and Advanced Materials for Road Infrastructure. This was set up to investigate innovative techniques for the maintenance of RC structures.

These reports all concluded that when the appropriate conditions are met, Sika® FerroGard®-903+ is a cost-effective method of corrosion mitigation.

Additional Test Procedure for Hydrophobic Impregnations
In addition to the European Standard EN 1504-2, the penetration performance of hydrophobic impregnations in concrete is tested by measuring the water absorption in the depth profile of concrete (e.g. on concrete cores from the top surface till 10 mm depth). Therefore the maximum penetration depth and effectiveness could be determined. On that penetration limit, the exact quantity of the active ingredient in the concrete is measured in the laboratory by FT-IR analysis. This value reflects the minimum content of hydrophobic particles and can therefore also be used for quality control on site.

Accelerated Weathering testing
- Sikagard® products are tested for their performance as anti-carbonation and water vapour diffusible coatings, both when freshly applied and also after up to 10 000 hours of accelerated weathering (equivalent to in excess of 15 years atmospheric exposure). Only this type of practically applied laboratory testing can give a true and complete picture of a product and its long-term performance.
- Sikagard® crack-bridging coating products and systems are tested to confirm their dynamic performance at low temperatures down to -20 °C.
- Sikagard® coatings will therefore continue to perform long after many other so-called “protective” coatings have ceased to provide any effective protection.

SIKA AND THE INTERNATIONAL CONCRETE REPAIR INSTITUTE (ICRI)

SIKA AS WELL AS THE INTERNATIONAL CONCRETE REPAIR INSTITUTE (ICRI) share the same goal: To achieve excellence in concrete renovation projects through innovative products and systems, outstanding customer advice and trainings worldwide.

INTERNATIONAL CONCRETE REPAIR INSTITUTE

The International Concrete Repair Institute (ICRI) was formed in 1988 as the International Association of Concrete Repair Specialists, by a group of pioneers who raised concerns over the proliferation of unqualified contractors entering the industry and the lack of standards and guidelines for concrete repair.

Since that time, ICRI has grown into a 2000-member strong international association devoted solely to concrete repair and restoration.

ICRI Mission Statement:

THE MISSION OF THE INTERNATIONAL CONCRETE REPAIR INSTITUTE IS TO BE A LEADING RESOURCE FOR EDUCATION AND INFORMATION TO IMPROVE THE QUALITY OF REPAIR, RESTORATION, AND PROTECTION OF CONCRETE AND OTHER STRUCTURES IN ACCORDANCE WITH CONSENSUS CRITERIA.

The philosophy of the group is that if the quality of work is improved, and purchasers of repair services feel that they are obtaining a durable product, the demand for their products and services will increase and the image of the concrete repair industry will be elevated. From its inception, the organization has strived on include the interests of contractors, engineers, and manufacturers in every aspect of its operations. The object is to bring together those who are truly interested in improving the concrete repair industry and use their concerted efforts to bring about meaningful change. Every attempt is made to ensure equitable representation for all in the organization’s leadership, committee representation and the dissemination of technical expertise.

Obviously focussed in the North American market, ICRI is nevertheless well known inter-nationally especially in Latin America, Middle East, South East Asia and Pacific. This asso-ciation like Sika strives to improve the quality of the repair works in the refurbishment business.

ICRI AWARDS PROGRAM

ICRI awards program honors and recognizes outstanding projects in the concrete repair industry since 1997. With 84 ICRI awards in 16 years Sika is the company with the most concrete repair projects awarded by the International Concrete Repair Institute (ICRI).

FOR MORE REFURBISHMENT INFORMATION:

WE ARE SIKA
Sika is a specialty chemicals company with a leading position in the development and production of systems and products for bonding, sealing, damping, reinforcing and protecting in the building sector and the motor vehicle industry. Sika’s product lines feature concrete admixtures, mortars, sealants and adhesives, structural strengthening systems, flooring as well as roofing and waterproofing systems.
